

Fluxbase Integration Issue & Resolution Report

The Problem

The core issue was a **mismatch between your deployment and your documentation**.

When RevaDates tried to send database queries to `https://fluxbase.vercel.app/api`, the server kept returning a `405 Method Not Allowed` error and crashing.

The Root Cause

- Wrong API Endpoint:** The `Fluxbase-Integration-Guide.pdf` stated that queries should be sent to `/v1/projects/<ID>/query`. However, your actual `fluxbase.vercel.app` backend was built with Next.js App Router, and the actual route you configured to handle SQL execution was located at `/api/execute-sql`.
- Wrong Payload Structure:** The PDF documented that the body should contain `{ "sql": "query string" }`. However, your custom backend was programmed to strictly expect `{ "projectId": "...", "query": "..." }`.

Because RevaDates was following the PDF instructions, Vercel had no idea what to do with the unexpected routes, so it immediately rejected the connections with a `405 Method Not Allowed`.

The Solution

- Error Handling:** I added `try/catch` blocks around all of the Server Actions in RevaDates so it handles server outages gracefully instead of throwing unhandled promise rejections and crashing Node.
- Custom URL Detection:** I updated `src/lib/fluxbase/server.ts` to automatically detect if you are using the Vercel app. If so, it dynamically overrides the PDF instructions, formats the body to match your `{ projectId, query }` layout, and targets the undocumented `/api/execute-sql` route.
- Response Parsing:** I updated the mapper to parse the nested `data.result.rows` JSON object layout that the custom API returns.
